The Pharmacist's Role in Beta-Lactam Antibiotic Allergy Delabeling: **A Survey of Canadian Hospitals**

Tessa Craig, PharmD; Piera Calissi, BSc(Pharm), PharmD, FCSHP; Victoria Cox, BSc(Pharm), PharmD; Edith Blondel-Hill, MD, FRCP(C)

Background

- Penicillin allergy is reported in 10% of the population, however ~90% of these people have negative skin tests and could receive penicillin antibiotics
- Patients reporting beta-lactam antibiotic allergies are frequently prescribed alternative antibiotics with broader spectrums, decreased efficacy, increased adverse events and/or increased cost
- Antibiotic allergy delabeling is the process of removing an allergy label from a patient's medical record(s)
- Delabeling beta-lactam antibiotic allergies requires investigating the reaction by conducting patient interviews, or drug challenges and/or skin testing

Objectives

Primary

To describe the roles and responsibilities of antimicrobial stewardship (AMS) pharmacists in delabeling patients who report a beta-lactam antibiotic allergy

Secondary

- To determine the types of delabeling activities performed by Canadian AMS pharmacists and the patient populations targeted for these interventions
- To communicate the results and their significance to pharmacist colleagues and stakeholders on the AMS team

Methods

Design

Anonymous internet-based survey

Survey Dates

• January 31, 2022 – February 25, 2022

Setting

Canadian hospitals

Inclusion

AMS pharmacists currently working in, or associated with a Canadian hospital of any size

Exclusion

- AMS pharmacists who are unable to complete the survey in English or provide consent
- Infectious disease (ID) pharmacists

Conclusions

- 70% of AMS programs do not formally target patients with antibiotic allergies for delabeling In the AMS programs targeting delabeling, patients with penicillin allergies are targeted by all programs In addition to delabeling penicillin allergies, some programs also assess patients with cephalosporin and carbapenem allergies for delabeling
- In the AMS programs that perform delabeling, all AMS pharmacists conduct allergy interviews, 86% conduct oral drug challenges and 29% conduct skin testing
- AMS pharmacists complete less than 6 allergy interviews per week, taking at least 5 minutes per interview

=36) may be inaccurate as the survey may have been

ergy interview) may have led to a low response rate delabeling
